

Finite Automata

What is a Finite Automaton?

- ◆ A formal system.
- ◆ Remembers only a finite amount of information.
- ◆ Information represented by its *state*.
- ◆ State changes in response to *inputs*.
- ◆ Rules that tell how the state changes in response to inputs are called *transitions*.

Informal Explanation

- ◆ Finite automata are finite collections of states with transition rules that take you from one state to another.
- ◆ Original application was sequential switching circuits, where the "state" was the settings of internal bits.
- ◆ Today, several kinds of software can be modeled by FA.

Representing FA

- ◆ Simplest representation is often a graph.
 - ◆ Nodes = states.
 - ◆ Arcs indicate state transitions.
 - ◆ Labels on arcs tell what causes the transition.

Example: Recognizing Strings Ending in "ing"

Example: Protocol for Sending Data

Tennis

- ◆ Like ping-pong, except you are very tiny and stand on the table.
- ◆ *Match* = 3-5 sets.
- ◆ *Set* = 6 or more games.

Scoring a Game

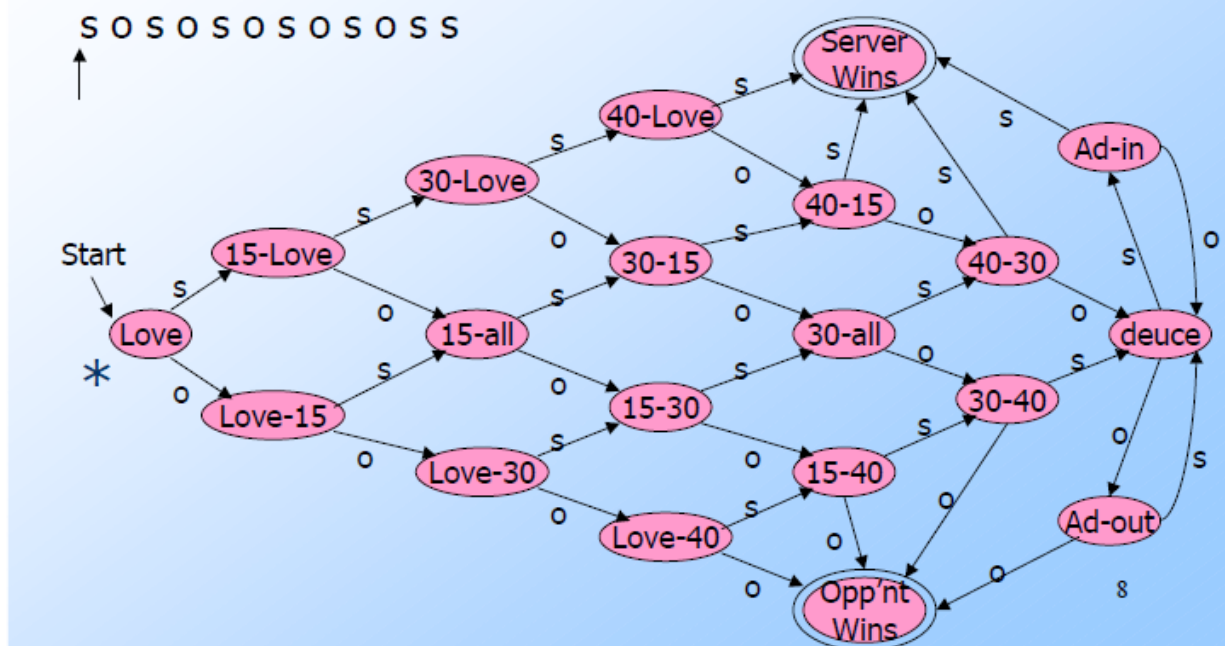

- ◆ One person serves throughout.
- ◆ To win, you must score at least 4 points.
- ◆ You also must win by at least 2 points.
- ◆ Inputs are s = "server wins point" and o = "opponent wins point."

Acceptance of Inputs

- ◆ Given a sequence of inputs (*input string*), start in the start state and follow the transition from each symbol in turn.
- ◆ Input is *accepted* if you wind up in a final (accepting) state after all inputs have been read.

Example: Processing a String

Language of an Automaton

- ◆ The set of strings accepted by an automaton A is the *language* of A .
- ◆ Denoted $L(A)$.
- ◆ Different sets of final states \rightarrow different languages.
- ◆ **Example:** As designed, $L(\text{Tennis}) =$ strings that determine the winner.
